

## Project #2 for the Biomedical Information Retrieval Course

Due: Oct 6 , 2026

### General Guideline

This homework is basically an individual homework. Each student has to do it all by himself (or herself). The final score will be evaluated from the system performance and individual demonstration.

### Homework Overview

First of all, implement the Zipf Distribution computation (or frequency spectrum for terms) for both a set of text documents from PubMed. The size of text document sets could range from 10 to 1000, depends on your intention. You have to preprocess the text index (token) set from document collection. Then, implement the *Porter's algorithm* as a functional module on your own software platform for the same set of text documents. Then, compare the difference.

Second part of this project is to implement the Word Embedding Technique(word2vec) for a set of text documents from PubMed with *same subject*. You have to preprocess the text set from document collection. In this project, you can choose one of the 2 basic computational models:

1. Continuous Bag of Word (CBOW): use a window of word to predict the middle word
2. Skip-gram (SG): use a word to predict the surrounding ones in window.

Window size is not limited. Computer languages are not limited.

In this project, basically your system or software platform will be able to compute text distribution from a set of documents. Match (or partial matching) process can be done using the dynamic programming-based *Edit distance* computation. Your retrieval results can be displayed in a format of indicating the location(s) and/or partial matching of the query keywords in each document, etc. Computer languages are not limited.

### System Description

1. I suggest that you can test your system in advanced using certain disease name, e.g. "GLP-1", which contains approximately 3000 documents. Each individual student builds its own system components using basic matching scheme from the IR course. *Spelling correction* is necessary for this project.
2. In the final evaluation, each individual should present system description, running results, and system demo to verify system performance.
